# Even for critical systems?

**2008, airplane system that failed to monitor technical problems was infected with malware**

## Spanair Flight 5022

From Wikipedia, the free encyclopedia

**Spanair Flight 5022** was a scheduled domestic passenger flight from [Barcelona–El Prat Airport](#) to [Gran Canaria Airport](#), Spain, via [Madrid–Barajas Airport](#) that crashed just after take-off from runway 36L at Madrid Airport at 14:24 CEST (12:24 UTC) on 20 August 2008. The aircraft was a [McDonnell Douglas MD-82](#), registration EC-HFP. Of the 172 passengers and crew on board, 154 died and 18 survived.<sup>[1][2]</sup>

### Malware [ edit ]

Spanish daily [El País](#) reported that, as revealed in an internal report issued by Spanair, [malware](#) which had infected the airline's central computer system used to monitor technical problems with its aircraft may have resulted in a failure to raise an alarm over multiple problems with the aircraft. A judge ordered the airline to provide all the computer system's logs from the days before and after the crash.<sup>[48][49][50]</sup>

# Why compromise a user's machine?

- Reason #1:
  - credentials: steal bank, business, gaming passwords

## **Trojan.Silentbanker.B Description**

[source: microsoft, 2008]

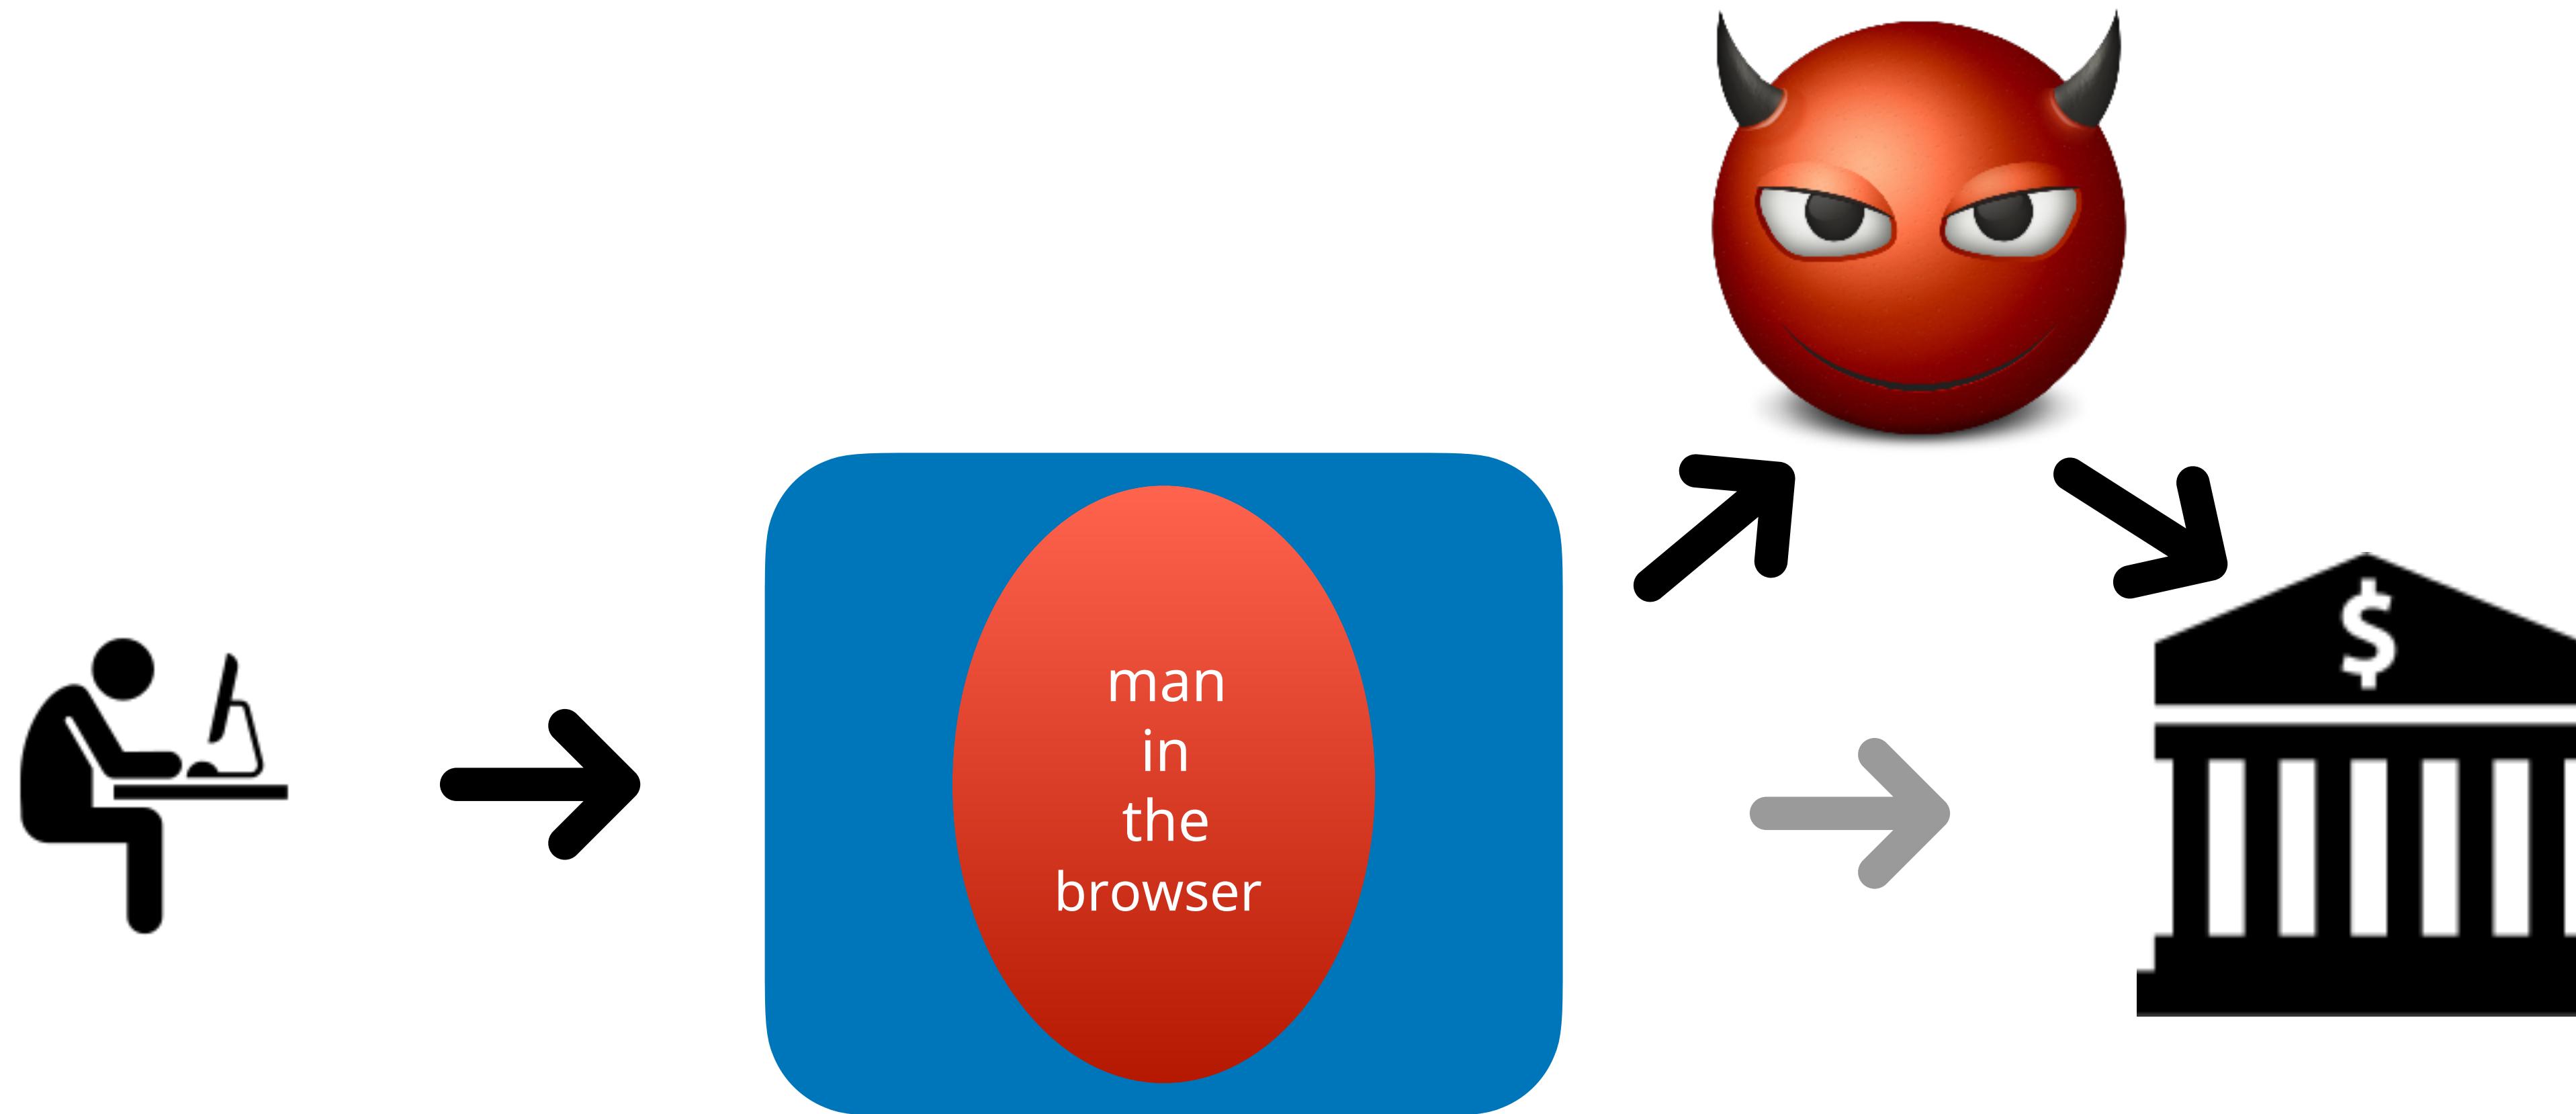

### **Type:** Trojan

Trojan.Silentbanker.B is an evolved Trojan parasite that is designed to secretly infect a computer in its efforts to seek out and steal online banking login information. Trojan.Silentbanker.B uses various methods to steal financial data from the hard drive of an infected PC and then send the information to a remote hacker.

Trojan.Silentbanker.B may also reduce the performance of an infected computer to the point that the administrator no longer has full control. It is essential that an infection as dangerous as Trojan.Silentbanker.B is removed at once.

# Why compromise a user's machine?

- Reason #1:
  - credentials: steal bank, business, gaming passwords

# Threat Spotlight: ZeuS (aka Zbot) Infostealer Trojan

RESEARCH & INTELLIGENCE / 04.29.20 / T.J. O'Leary

## Threat Spotlight: ZeuS (aka Zbot) Infostealer Trojan

ZeuS (aka Zbot) is an infamous and successful information stealing Trojan. First detected in 2007, the malware's primary focus is stealing financial/banking information and user credentials from individuals and organizations. Its exploits resulted in [the theft of billions of dollars on a global scale](#)<sup>[1]</sup>. ZeuS crimeware kits vary in complexity with costs ranging from free to several thousand dollars (for [later versions with added functionality](#))<sup>[2]</sup>.

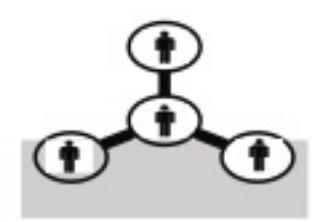

This completes the infection process. The target PC is now an active member of a ZeuS botnet and will execute any script commands sent by the botnets master. The infected processes will perform web injects by hooking the Windows API functions responsible for sending and receiving HTTP(S) data, Unsuspecting users will provide confidential information which Zeus then sends to the configured C2 or drop server.

## Spyware financial

## Cyber Theft Ring

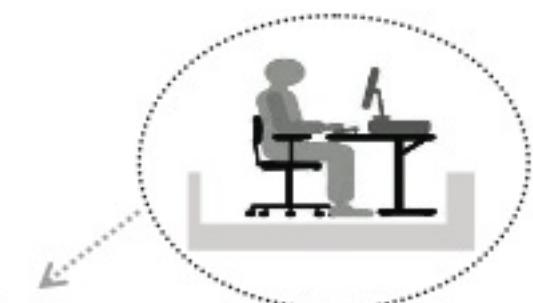

Malware exploiters purchase malware and use it to steal victim banking credentials. They launch attacks from compromised machines that allow them to transfer stolen funds and deter any tracking of their activities.

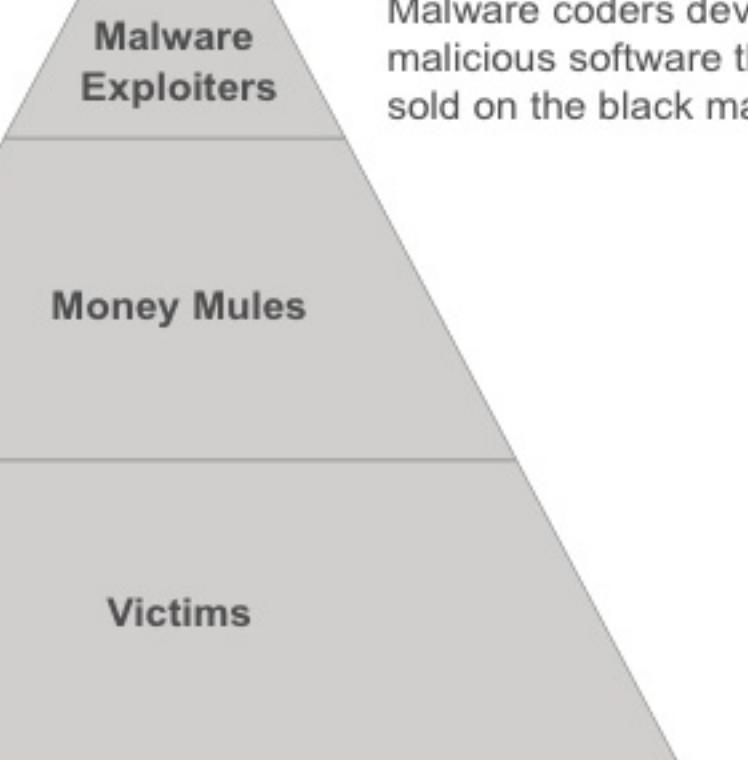

Money mule networks are comprised of individuals engaged in the transfer of stolen funds who retain a percentage for their services.

Victims include individuals, businesses, and financial institutions.

Malware coders develop malicious software that is sold on the black market.

# Banking Trojans: A Reference Guide to the Malware Family Tree

## ZEUS

Continuously spawning variants, legacy Zeus is known to grab user credentials, alter webpage forms, and redirect to fake sites. The latest variant generates income through a pay-per-click model.

## GOZI

Logging keystrokes, old-school Gozi steals users' login credentials and redirects users to fake websites to hijack banking transactions. It's known for its evasion techniques.

## CARBERP

With ties to organized crime, Carberp logs keystrokes, hides instances of itself, and spoofs banking websites, all intending to steal users' banking credentials and money.

## SPY-EYE

SpyEye targeted Windows users running some of the most popular web browsers. It tried to kill Zeus and stole users' credentials.

\* Absorbed Zeus code when Zeus author retired.

## SHYLOCK

This Merchant of Venice captured users' online banking credentials and then tricked them into transferring funds to attacker-controlled accounts.

## TINBA

As the smallest banking trojan known (20 KB), Tinba uses web-injects and typically runs geo-specific campaigns.

\* Shared nearly identical webinjests with Gozi.

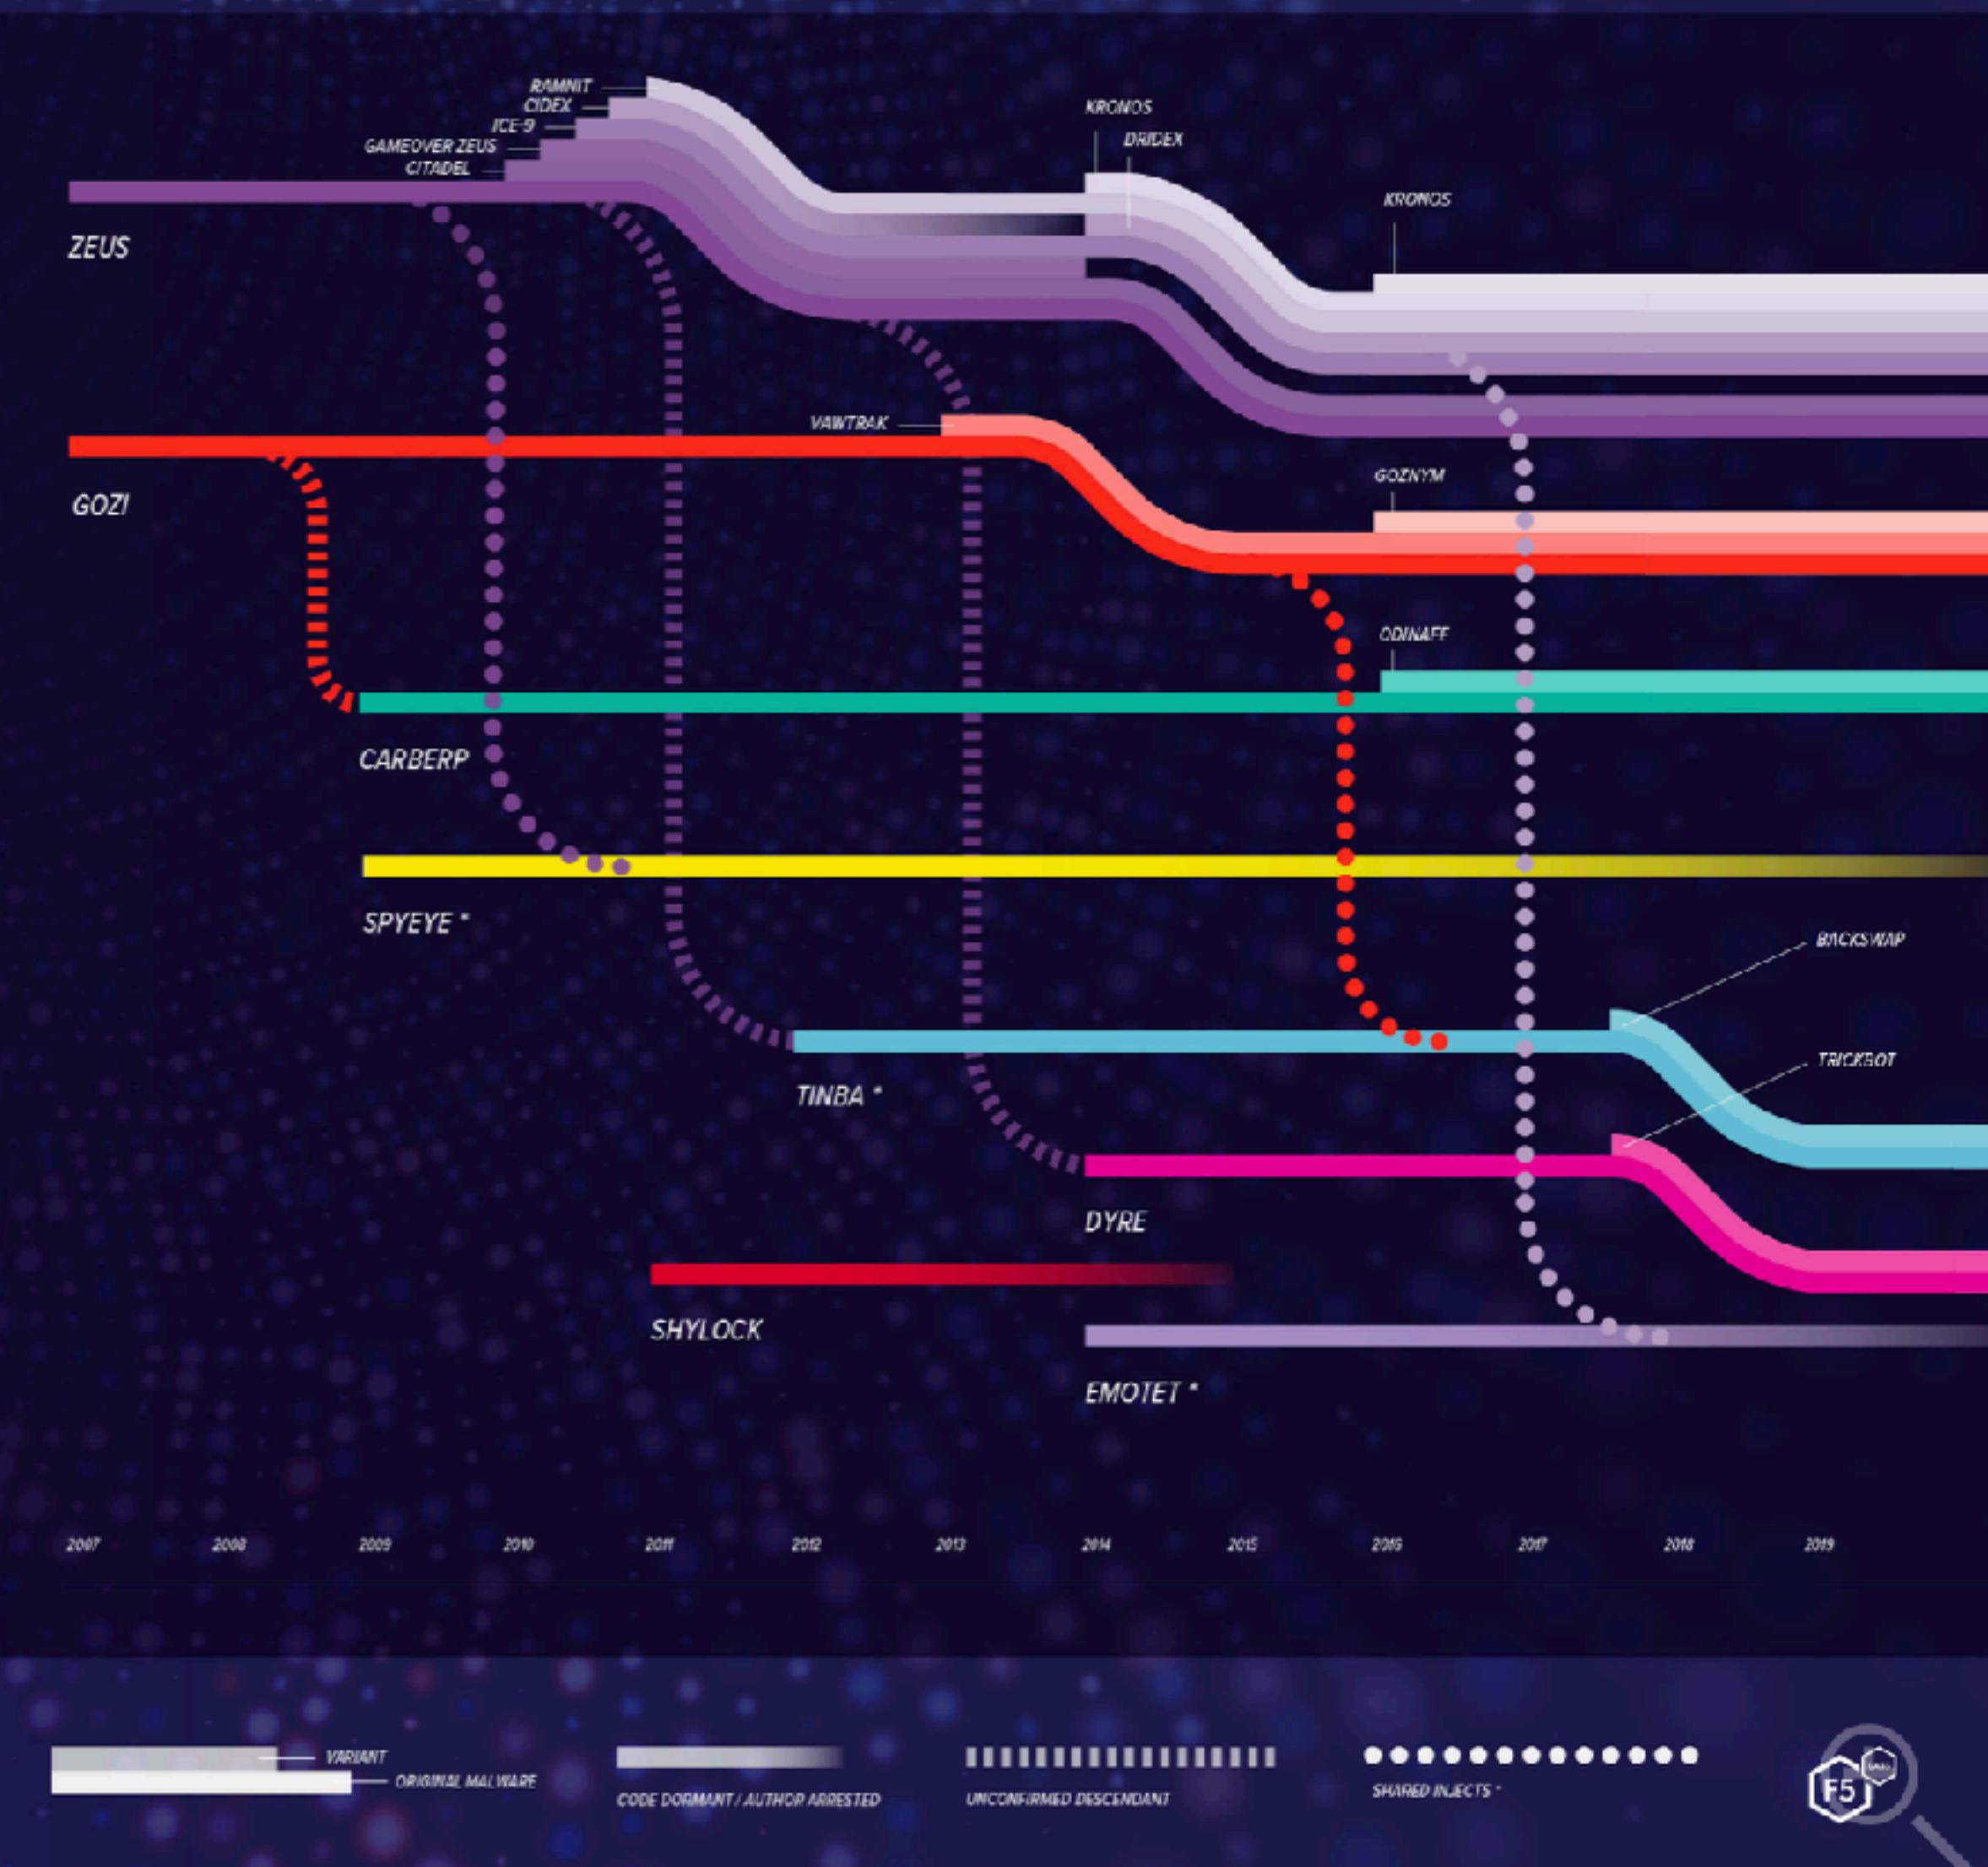

## DYRE

The first to use completely fake login pages, server-side web-injects, and a modular architecture, Dyre was also known for its unique fraud techniques, crypto evolution, and stealth capabilities.

## EMOTET

Emotet began as a banking trojan and later incorporated malware delivery services that enabled it to install other banking trojans.

\* Drops Dridex as a payload.

# German-made FinSpy spyware found in Egypt, and Mac and Linux versions revealed

25 September 2020, 12:00 UTC

## Summary:

- FinSpy is a commercial spyware suite produced by the Munich-based company FinFisher Gmbh. Since 2011 researchers have documented numerous cases of targeting of Human Rights Defenders (HRDs) - including activists, journalists, and dissidents with the use of FinSpy in many countries, including [Bahrain](#), [Ethiopia](#), UAE, and more. Because of this, Amnesty International's Security Lab tracks FinSpy usage and development as part of our continuous monitoring of digital threats to Human Rights Defenders.

Also for mobile, and available on the market!

# FinFisher

From Wikipedia, the free encyclopedia

**FinFisher**, also known as **FinSpy**,<sup>[1]</sup> is surveillance software marketed by Lench IT Solutions plc, which markets the spyware through law enforcement channels.<sup>[1]</sup>

# Pegasus (spyware)

From Wikipedia, the free encyclopedia

**Pegasus** is [spyware](#) developed by the Israeli [cyber-arms company NSO Group](#) that can be covertly installed on [mobile phones](#) (and other devices) running most<sup>[1]</sup> versions of [iOS](#) and [Android](#).<sup>[2]</sup>

Pegasus is able to exploit iOS versions up to 14.7, through a [zero-click exploit](#).<sup>[1]</sup> As of 2022, Pegasus was capable of [reading text messages](#), [tracking calls](#), [collecting passwords](#), [location tracking](#), accessing the target device's microphone and camera, and harvesting information from apps.<sup>[3][4]</sup>

The spyware is named after [Pegasus](#), the winged horse of [Greek mythology](#). It is a [Trojan horse](#) computer virus that can be sent "flying through the air" to infect cell phones.<sup>[5]</sup>

Pegasus was discovered in August 2016 after a failed installation attempt on the [iPhone](#) of a [human rights activist](#) led to an investigation revealing details about the spyware, its abilities, and the [security vulnerabilities](#) it exploited. News of the spyware caused significant media coverage. It was called the "most sophisticated" smartphone attack ever, and was the first time that a malicious remote exploit used [jailbreaking](#) to gain unrestricted access to an iPhone.<sup>[6]</sup>

The spyware has been used for surveillance of anti-regime activists, journalists, and political leaders from several nations around the world.<sup>[7]</sup> In July 2021, the investigation initiative [Pegasus Project](#), along with an in-depth analysis by [human rights](#) group [Amnesty International](#), reported that Pegasus was still being widely used against high-profile targets.<sup>[1]</sup>

## December 2015 Ukraine power grid cyberattack

From Wikipedia, the free encyclopedia

On 23 December 2015, hackers compromised information systems of three energy distribution companies in [Ukraine](#) and temporarily disrupted the electricity supply to consumers. It is the first known successful [cyberattack](#) on a power grid.

Stuxnet, discovered by Sergey Ulasen, initially spread via Microsoft Windows, and targeted Siemens [industrial control systems](#). While it is not the first time that hackers have targeted industrial systems,<sup>[25]</sup> nor the first publicly known intentional act of [cyberwarfare](#) to be implemented, it is the first discovered [malware](#) that spies on and subverts industrial systems,<sup>[26]</sup> and the first to include a [programmable logic controller](#) (PLC) rootkit.<sup>[27][28]</sup>

The **Democratic National Committee cyber attacks** took place in 2015 and 2016, in which Russian [computer hackers](#) infiltrated the [Democratic National Committee](#) (DNC) [computer network](#), leading to a [data breach](#). [Cybersecurity](#) experts, as well as the U.S. government, determined that the [cyberespionage](#) was the work of Russian intelligence agencies.

# Commit users

- Servers that distribute software allow you to disseminate *malware*:
  - Example: SolarWinds, monitoring tools
- Web servers allow you to compromise vulnerable browsers:
  - Example: MPack Server side toolkit for “website defacing”

The screenshot shows a web browser window with the URL "en.wikipedia.org" in the address bar. The main content is the article "2019–2020 supply chain attacks". A section titled "SUNBURST" is highlighted, with a sub-section "Main articles: 2020 United States federal government data breach and Supply chain attack". Below this, a paragraph describes the SolarWinds Orion software breach.

## 2019–2020 supply chain attacks [ edit ]

### SUNBURST [ edit ]

Main articles: [2020 United States federal government data breach](#) and [Supply chain attack](#)

On December 13, 2020, [The Washington Post](#) reported that multiple government agencies were breached through SolarWinds's Orion software (archived website copy). The company stated in an [SEC](#) filing that fewer than 18,000 of its 33,000 Orion customers were affected,

## MPack (software)

From Wikipedia, the free encyclopedia

*Not to be confused with [Mpack \(unix\)](#), the command-line utility for manipulating MIME-encoded messages, or the [MPACK arbitrary-precision arithmetic LAPACK library](#).*

In computer security, MPack is a PHP-based malware kit produced by Russian crackers. The first version was released in December 2006. Since then a new version is thought to have been released roughly every month. It is thought to have been used to infect up to 160,000 PCs with keylogging software. In August 2007 it was believed to have been used in an attack on the web site of the Bank of India which originated from the Russian Business Network.

## What is Zerodium?

Zerodium is the world's leading exploit acquisition platform for premium zero-days and advanced cybersecurity research.

Founded in 2015 by cybersecurity veterans with unparalleled experience in zero-day research and exploitation, Zerodium is now a global community of independent security researchers working together to provide the most powerful cybersecurity capabilities to institutional customers.

Zerodium pays the highest bounties in the market to reward researchers and acquire their zero-day discoveries. We believe that this is the only way to support the zero-day research community and capture the most advanced and innovative research from all around the world.

## What is the difference between ZERODIUM and other bug bounty programs?

## How is the acquired security research used by Zerodium?

## Who are Zerodium's customers?

Zerodium customers are government organizations (mainly from Europe and North America) in need of advanced zero-day exploits and cybersecurity capabilities.

At Zerodium we take ethics very seriously and we choose our customers very carefully through a very strict due diligence and vetting process. Access to acquired zero-day research is highly restricted and is limited to a very small number of government clients.

Furthermore, Zerodium does not have any sales partners or resellers, meaning that our solutions are only available through our direct sales channel.

# How do we guarantee security?

# "Safety"?

- a common definition
  - “The property of a system that behaves as expected”
- This definition does not say what the system should or should not do:
  - There is no universal definition or test

“Computer security, cybersecurity or information technology security (IT security) is the protection of computer systems and networks from information disclosure, theft or damage to their hardware, software, or electronic data, as well as from the disruption or misdirection of the services they provide.”

*- Wikipedia*

“Software security is about integrating security practices into the way you build software, not integrating security features into your code”

*- Gary McGraw*

“System that remains dependable in the face of malice”

*- Ross Anderson*

# A different way of thinking

- security is relative
  - “Security” by itself means nothing.
  - Security depends on who defines it
- Security changes depending on the context
  - Everything, including the terminology used, depends on the specific application
- Security is defensive
  - It is defined by the negative: everything that is not good cannot happen
  - Much harder than ensuring that something specific happens

## an absurd example

- This system is "safe" when:
  - The security objective is prevent a car from passing on the road with the gate ?

# actors

- Actors or participants are entities that intervene in the system:
  - People, organizations, companies, machines, ...
  - Security is defined from the point of view of these actors
- It is often depositedconfidence in some actors/components
  - eg, Trusted Third Party (TTP), Trusted Agent (TA)
  - "Secure" systemif confidence assumption is verified
    - if no? e.g. defense in depth
- In others the actors are potential attackers (external/internal)

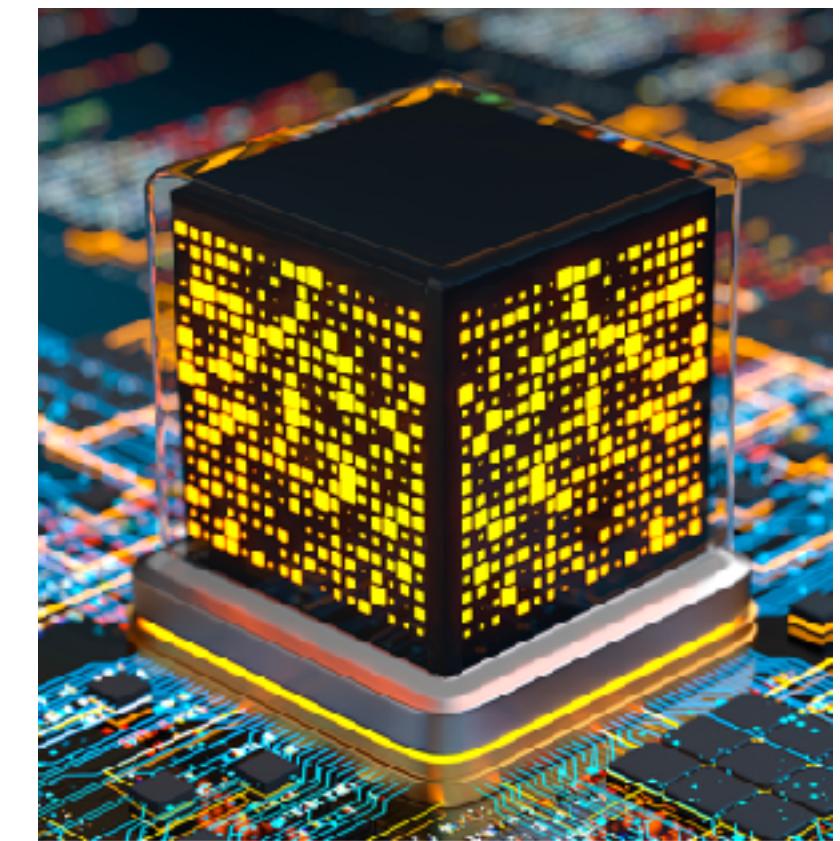

# Opponent/Forward

- In computer security, we analyze the behavior of systems when they interact with adversaries/attackers:
- Actors with an explicit intention to misuse the system/resources or to make their use impossible

# Opponent/Forward

- No system is safe from all adversaries

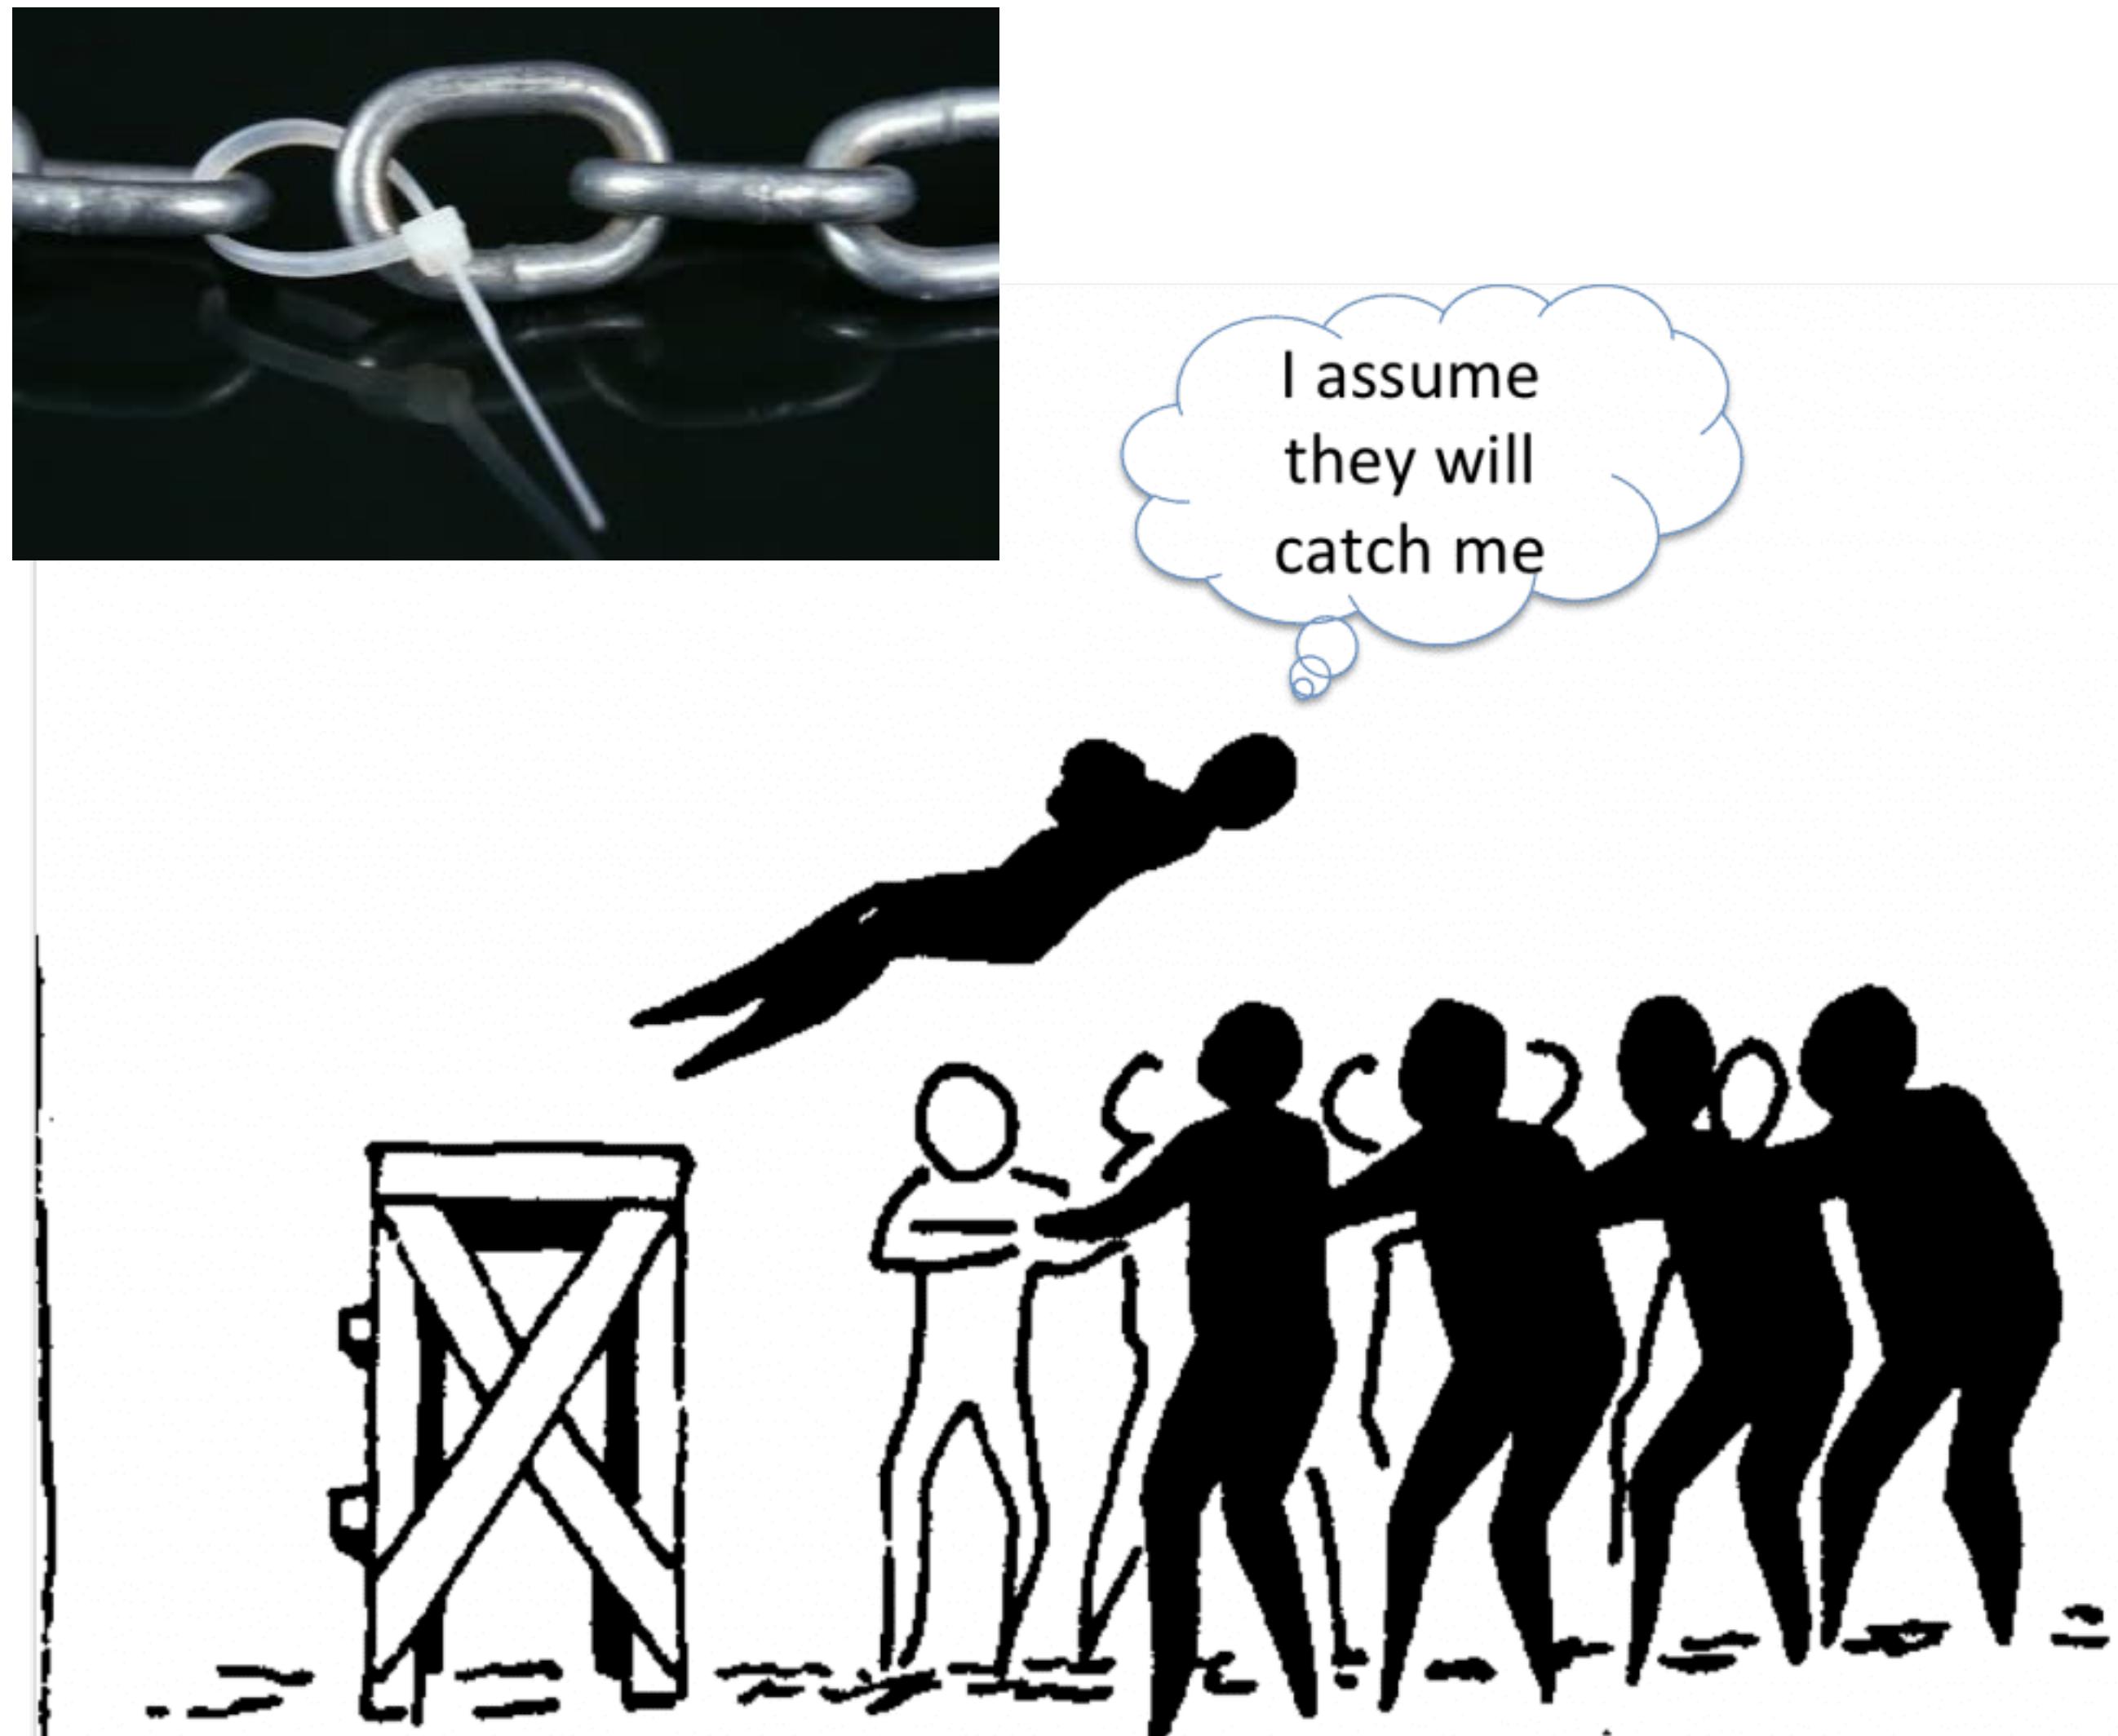

# Opponent/Forward

- It is critical to know our opponent (motivation, capabilities, access):
  - “Script-kiddies” (curious but incapable)
  - Occasional attackers who aim to understand the systems
  - Persons with intent to cause harm/destruction
  - Organized and technically sophisticated groups (eg, cyber crime)
  - Competitors (industrial espionage)
  - Countries/States/Governments

# Opponent/Forward

- You need to think like an opponent/attacker:
  - Always look for the weakest link
  - Identify trust assumptions underlying security
    - Are they valid?
  - Look at the "out of the box" system
    - Whoever designs a system is always "stuck" with what he is supposed to do.

# The value of skepticism

**the characteristic  
most important is  
keep skepticism!**

<https://www.usenix.org/conference/usenixsecurity18/presentation/mickens>
